

Joint Parsing and Alignment with Weakly Synchronized Grammars

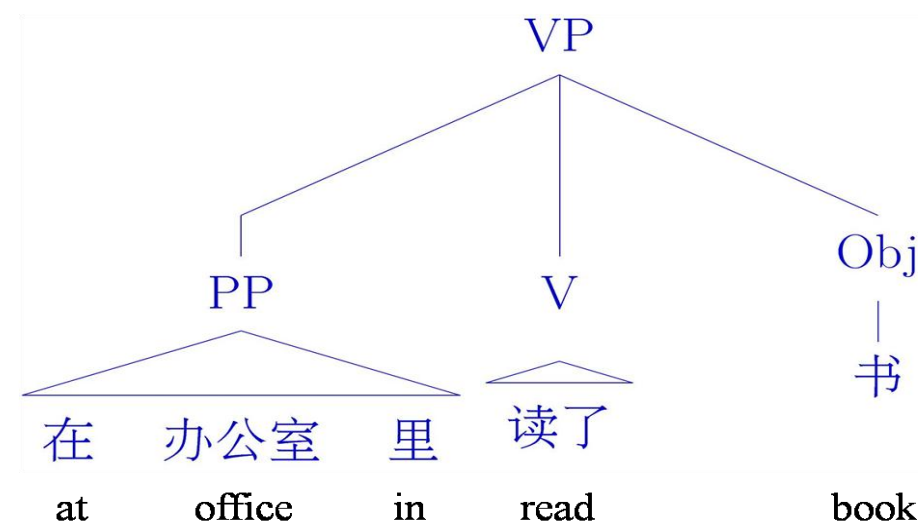

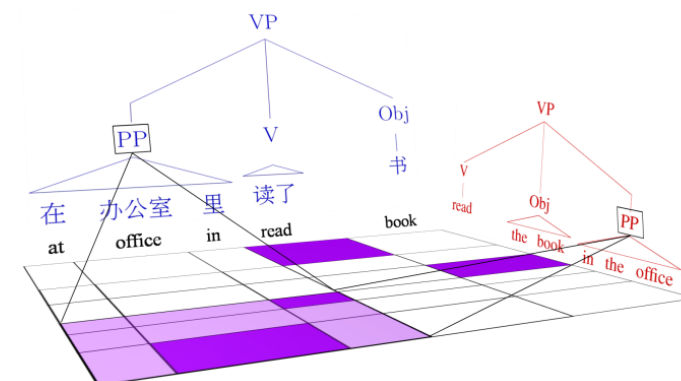

David Burkett, John Blitzer, & Dan Klein

Statistical MT Training Pipeline

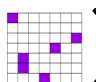

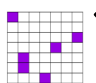

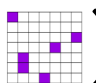

- 1) Align sentence pairs (GIZA++)
- 2) Parse English sentences (Berkeley parser)
Parse Foreign sentences
- 3) Extract rules (Galley et al. 2006)
- 4) Tune discriminative parameters

Joint model for (1) & (2)

Syntactic Correspondences

Build a model $p_{\theta}(\triangle, \triangle, \text{grid} | \text{中文}, \text{EN})$

Correspondence via Synchronous Grammars

Correspondence Model & Feature Types

$$p_{\theta}(\text{blue triangle}, \text{red triangle}, \text{grid} \mid \text{EN}, \text{中文})$$

Feature type 1: Word Alignment

$$\phi(\text{grid}, \text{EN}, \text{中文})$$

办公室 office [HBDK09]

Feature type 3: Correspondence

$$\phi(\text{blue triangle}, \text{red triangle}, \text{grid})$$

Feature type 2: Monolingual Parser

$$\phi(\text{red triangle}, \text{EN})$$

Estimating θ

- Set θ to maximize the log-likelihood of the correct parses & alignments

$$\log p_{\theta} (\triangleleft, \blacktriangle, \text{grid} \mid \text{EN}, \text{中文}) = \langle \theta, \phi(\triangleleft, \blacktriangle, \text{grid}, \text{EN}, \text{中文}) \rangle - \log Z(\text{EN}, \text{中文})$$

- $Z(\text{EN}, \text{中文})$ normalizes p_{θ} to sum to 1

$$Z(\text{EN}, \text{中文}) = \sum_{\triangleleft, \blacktriangle, \text{grid}} \exp \{ \langle \theta, \phi(\triangleleft, \blacktriangle, \text{grid}, \text{EN}, \text{中文}) \rangle \}$$

Computing $Z(\text{EN}, \text{中文})$

$$Z(\text{EN}, \text{中文}) = \sum_{\triangle, \blacktriangle, \text{grid}} \exp \{ \langle \theta, \phi(\triangle, \blacktriangle, \text{grid}, \text{EN}, \text{中文}) \rangle \}$$

Individual \sum_{\triangle} , \sum_{\blacktriangle} , \sum_{grid} have polynomial-time dynamic programming algorithms

Correspondence features tie pieces together

Computing $Z(\text{EN}, \text{中文})$ exactly is intractable

Approximating $Z(\text{EN}, \text{中文})$: Mean Field

- Exploit tractability in individual models: $\sum_{\text{blue triangle}} \sum_{\text{red triangle}} \sum_{\text{grid}}$
- Factored approximation: $p_{\theta}(\text{blue triangle}, \text{red triangle}, \text{grid} | \text{EN}, \text{中文}) \approx q(\text{blue triangle})q(\text{red triangle})q(\text{grid})$
- Set q to minimize $KL(q(\text{blue triangle})q(\text{red triangle})q(\text{grid}), p_{\theta}(\text{blue triangle}, \text{red triangle}, \text{grid} | \text{EN}, \text{中文}))$

Algorithm

1) Initialize $q(\text{blue triangle})$ $q(\text{red triangle})$ $q(\text{grid})$ separately

2) Iterate:

$$q(\text{blue triangle}) \propto \exp \{ \langle \theta, \phi(\text{blue triangle}, E_q(\text{red triangle}), E_q(\text{grid})) \rangle \}$$

$$q(\text{red triangle}) \propto \exp \{ \langle \theta, \phi(E_q(\text{blue triangle}), \text{red triangle}, E_q(\text{grid})) \rangle \}$$

$$q(\text{grid}) \propto \exp \{ \langle \theta, \phi(E_q(\text{blue triangle}), E_q(\text{red triangle}), \text{grid}) \rangle \}$$

Large scale inference

We can approximate $Z(\text{EN}, \text{中文})$ in polynomial time, but . . .

\sum Sum over possible alignments is an $O(n^6)$ algorithm.

But computers are fast, right?

- Medium-length sentences are 50 words long
- Small translation data sets are 250,000 sentences
- ~4 quadrillion operations (See [\[BBK10, HBDK09\]](#) for speedup details)
